Number.isNaN()

The **Number.isNaN()** method determines whether the passed value is [NaN](#) and its type is [Number](#). It is a more robust version of the original, global [isNaN\(\)](#).

Try it

JavaScript Demo: Number.isNaN()

```
1 function typeOfNaN(x) {
2   if (Number.isNaN(x)) {
3     return 'Number NaN';
4   }
5   if (isNaN(x)) {
6     return 'NaN';
7   }
8 }
9
10 console.log(typeOfNaN('100F'));
11 // expected output: "NaN"
12
13 console.log(typeOfNaN(NaN));
14 // expected output: "Number NaN"
15
```

Run ›

Reset

Syntax

Number.**isNaN**(value)

Parameters

value

The value to be tested for [NaN](#).

Return value

The boolean value `true` if the given value is a number with value [NaN](#). Otherwise, `false`.
