String.prototype.split()

The **split()** method takes a pattern and divides a [String](#) into an ordered list of substrings by searching for the pattern, puts these substrings into an array, and returns the array.

Try it

JavaScript Demo: String.split()

```
1 const str = 'The quick brown fox jumps over the lazy dog.';
2
3 const words = str.split(' ');
4 console.log(words[3]);
5 // expected output: "fox"
6
7 const chars = str.split('');
8 console.log(chars[8]);
9 // expected output: "k"
10
11 const strCopy = str.split();
12 console.log(strCopy);
13 // expected output: Array ["The quick brown fox jumps over the lazy dog."]
14
```

Run ›

Reset

Syntax

```
split()
split(separator)
split(separator, limit)
```

Parameters

separator Optional

The pattern describing where each split should occur. Can be a string or an object with a [Symbol.split](#) method — the typical example being a [regular expression](#). If undefined, the original target string is returned wrapped in an array.
